Weighted Average<sup>2</sup>

1. Suppose we have a collection of 15 marbles in a container. 40 % of the marbles are red and 60 % of the marbles are black. The orange marbles weigh 6.00 grams and the black marbles weigh 8.00 grams.

- a) Calculate the average mass of the marbles in the container. (clearly show how you arrived at your answer.)

$$\# \text{ of red marbles} = 15 * \left( \frac{40 \text{ red marbles}}{100 \text{ marbles}} \right) = 6 \text{ red marbles}$$

$$\# \text{ of black marbles} = 15 * \left( \frac{60 \text{ black marbles}}{100 \text{ marbles}} \right) = 9 \text{ black marbles}$$

$$\frac{6.00 + 6.00 + 6.00 + 6.00 + 6.00 + 6.00 + 8.00 + 8.00 + 8.00 + 8.00 + 8.00 + 8.00 + 8.00 + 8.00 + 8.00 \text{ grams}}{15 \text{ marbles}}$$

$$= 7.2 \text{ grams}$$

or

$$\text{average mass} = \frac{6 \text{ RM} * 6.00 \text{ grams} + 9 \text{ BM} * 8.00 \text{ grams}}{15 \text{ marbles}}$$

$$= \frac{108.0 \text{ grams}}{15 \text{ marbles}} = 7.20 \text{ grams}$$

- b) Do any marbles in the container have the same mass as the average mass?

**No the masses of the two marbles is 6.00 g (red) or 8.00 grams (black).  
There are no marbles with a mass of 7.20 grams.**

2. Suppose we have another collection of 40 marbles in a different container. 40 % of the marbles are red and 60 % of the marbles are black. The orange marbles weigh 6.00 grams and the black marbles weigh 8.00 grams.

- a) Calculate the average mass of the marbles in the container.

$$\text{average mass} = \frac{40 * 0.40 * 6.00 \text{ grams} + 40 * 0.60 * 8.00 \text{ grams}}{40 \text{ marbles}}$$

$$= \frac{288. \text{ grams}}{40 \text{ marbles}} = 7.20 \text{ grams}$$

3. Outline your strategy for calculating the average mass of a collection of orange and black marbles if the total number of marbles is not know.

---

<sup>2</sup> Inspired by Moog, R.S. and Farrell, J. J. Chemistry A Guided Inquiry. John Wiley, Sons. New York, 1996. Page 5.

We can re-write the equation used in Q1 and Q2 using the variable  $T_M$  for the total number of marbles in the sample; FA for the fractional abundance for each marble, MM for the marble mass.

$$\text{average mass} = \frac{T_M * FA_{\text{red}} * MM_{\text{red}} + T_M * FA_{\text{black}} * MM_{\text{black}}}{T_M}$$

$$\text{average mass} = \frac{T_M * 0.40 * 6.00 \text{ grams} + T_M * 0.60 * 8.00 \text{ grams}}{T_M}$$

factoring the numerator, we have

$$\text{average mass} = T_M * \frac{0.25 * 5.00 \text{ grams} + 0.75 * 7.00 \text{ grams}}{T_M}$$

the total marbles cancels and the equation reduces to,

$$\text{average mass} = 0.40 * 6.00 \text{ grams} + 0.60 * 8.00 \text{ grams}$$

So we see that the total number of marbles cancels out of the equation.

$$\text{average mass} = \text{fraction of marbles}_1 * \text{mass of marble}_1 + \text{fraction of marbles}_2 * \text{mass of marble}_2$$

4. Suppose we have a collection of marbles in a container. 20 % of the marbles are orange and 80 % of the marbles are white. The orange marbles weigh 4.00 grams and the white marbles weigh 10.00 grams.
  - a) Calculate the average mass of the marbles in the container.

We can re-write the equation used in Q3 using the variable  $T_M$  for the total number of marbles in the sample.

$$\text{average mass} = \frac{T_M * 0.20 * 4.00 \text{ grams} + T_M * 0.80 * 10.00 \text{ grams}}{T_M}$$

factoring the numerator, we have

$$\text{average mass} = T_M * \frac{0.20 * 4.00 \text{ grams} + 0.80 * 10.00 \text{ grams}}{T_M}$$

the total marbles cancels and the equation reduces to,

$$\text{average mass} = 0.20 * 4.00 \text{ grams} + 0.80 * 10.00 \text{ grams} = 8.80 \text{ grams}$$

So we see that the total number of marbles cancels out of the equation.

$$\text{average mass} = \text{fraction of marbles}_1 * \text{mass of marble}_1 + \text{fraction of marbles}_2 * \text{mass of marble}_2$$

5. The element boron is composed of two different isotopes,  $^{10}\text{B}$  and  $^{11}\text{B}$ . The percent abundance of  $^{10}\text{B}$  is 19.78 % and the percent abundance of  $^{11}\text{B}$  is 80.22 %. The relative atomic mass of  $^{10}\text{B}$  is 10.01294 u and the relative atomic mass of  $^{11}\text{B}$  is 11.00931 u. Calculate the (relative weighted) average atomic mass of boron.

**The equation we derived in Q3 can now be expressed in terms of isotopic mass and fractional abundance of the isotope.**

$$\text{average mass} = \Sigma(\text{fraction abundance}_i * \text{isotopic mass}_i)$$

$$\text{average mass} = \text{fraction abundance}_1 * \text{isotopic mass}_1 + \text{fraction abundance}_2 * \text{isotopic mass}_2$$

**Substituting the data from this problem,**

$$\text{average mass} = 0.1978 * 10.01294 \text{ u} + 0.8022 * 11.00931 \text{ u} = 10.81 \text{ u}$$

6. If you could reach in and pick a single atom from a sample of boron what would be the most probable mass of the atom of boron you selected. Explain.

**The most probable mass of a boron atom is 11.00931 u since that isotope has the highest percentage abundance.**
